# **Generating Humor With A Sieve\***

Extending Transformer-based Humor Generation by Leveraging Similarity Metrics

Joshua Dalin<sup>1</sup>, Mihir Sharma<sup>2</sup>, Sumedh Rasal<sup>3</sup> and Thomas Dahlstrom<sup>4</sup>

Abstract—Humor is vital to social interaction. Existing approaches to humor generation have been unsuccessful in producing consistently humorous content without restriction to narrow templates. We use a transformer-based neural network to generate a large set of humorous content, from which the best candidates are selected using a novel humor classification algorithm. Our approach allows selection of humorous content using disparate humor data sets, and generation of humorous.

## I. INTRODUCTION

Humor generation is the automatic creation of jokes or brief, humorous anecdotes by using one or multiple methodologies of text generation. The reason that there are different ways of producing humor and in varying different types of jokes is that there is currently "no theory of humor which is sufficiently precise, detailed, and formal to be implementable" [1]. The existing humor generation methods can be generally categorized as using either templates or neural networks [2]. A template will be used to produce jokes where a portion of the text is predictable, like a knock knock joke, or an "I like my X like I like my Y" joke. Neural network approaches produces humor using various joke and word associations the network was trained upon in a provided corpus.

Humor generation has been a long time goal of AI researchers. Some have even said in passing that an AI with distinct humor capabilities would serve as a benchmark for the Turing test. In light of that, humor in virtual assistants would help the human-machine bond that they try to create (smart phones could send quips along with information about the weather) [3]. The creation of humorous writing could be aided with humor generation in that additional jokes or fresh takes on a subject could be created to assist writers [3]. The creation of new technologies to generate humor also further the outcome of a "grand unifying theory of humor" [3].

\*This work was completed as part of the Humor Genome VIP at the Georgia Institute of Technology

## II. RESEARCH QUESTION

Can generalized (type of joke agnostic) humor be generated using an extension of existing Transformer Neural Network approaches, by training a Neural Network on metrics of similarities between words in jokes?

## III. METHODS

# A. Transformer Architecture

The generation of jokes prior to their analysis and classification is done by utilizing a pre-existing transformer model. A transformer is a type of NLP architecture which calculates self-attention multiple times in addition to feed-forward networks, so that it can better process context in sequential inputs. This applies to our use-case as a large proportion of jokes rely on some form of context-based humor to be considered funny. We used the GPT-2 (Generative Pre-trained Transformer 2) model as the base for our joke-generation model. Using the Hugging Face library, we were able to fine-tune the model so that, in addition to the large English dataset it was pre-trained on, the model trained for 3 epochs on a subset of jokes scraped from r/jokes and r/shortjokes. From here, we were able to have the model output a variety of different jokes, separated by newline tokens.

## B. Novel Classifier Architecture

The Novel Classifier creates a 2D NumPy array for each candidate phrase. The rows are composed of histograms representing the normalized distribution of similarities between each noun in the phrase, with each other noun in the phrase.

Thus, if we let  $N = [n_1, n_2, ...n_i]$  be a set containing all nouns n in the phrase, if k is the number of nouns in the phrase, m is the similarity metric used, v is the value of the bin in a given range (a, b), then:

$$M = f(m) = \begin{cases} 1 & \text{if } m(n_i, n_j) \in (a, b) \\ 0 & \text{if } m(n_i, n_j) \notin (a, b) \end{cases}$$
$$v = \frac{\sum_{i=1}^k \sum_{j=1}^k M}{k^2}$$

The following steps are followed on data input into the novel neural network classifier:

- 1) The input is a list of strings. Each string represents a phrase which may or may not be a joke.
- 2) Each string is tokenized using the nltk word\_tokenize() function.
- A new string composed of each noun in the phrase is generated to be used as input. Each noun is only used once.

- 4) For each of the path, wup, and lch similarity metrics (described below), a 2D NumPy array is created.
- 5) Each element in the NumPy array consists of the numerical similarity between each noun in the phrase, and each other noun in the phrase. As there may be multiple synsets (meanings) for each noun, a list of numerical similarities for all possible combinations of synsets is created. The smallest similarity is selected.
- 6) For each of the 3 numpy arrays (one for each similarity metric), a histogram consisting of 3 bins is created, normalized between 0-1.
- 7) Each of those histograms is appended to a list, which is used as input into a neural network.
- 8) The neural network outputs a confidence level between 0-1. A confidence close to 1 indicates high confidence the input is a joke. A confidence close to 0 indicates high confidence the input is not a joke. A confidence close to 0.5 indicates the network is uncertain whether the input is a joke or not.

The TensorFlow [10] based Keras [11] library Sequential architecture was used to build the neural network. The network consists of three Dense layers. The first two layers are composed of 9 neurons each, and use the Rectified Linear Unit (ReLU) activation function. The final, output layer is composed of 1 neuron using the Sigmoid activation function.

# C. Control Classifier Architecture

The model architecture, shown in figure 1, is a slight variant of the CNN architecture of Collobert et al. (2011). We have described the process by which one feature is extracted from one filter. The model uses multiple filters (with varying window sizes) to obtain multiple features. These features form the penultimate layer and are passed to a fully connected softmax layer whose output is the probability distribution over labels.

In one of the model variants, we experiment with having two 'channels' of word vectors—one that is kept static throughout training and one that is fine-tuned via back-propagation. In the multi-channel architecture, each filter is applied to both channels and the results are added to calculate 'ci' in equation. The model is otherwise equivalent to the single channel architecture. [4]

# D. Similarity Metrics

WordNet [6] contains an inheritance tree graph between words, with the most similar words being closest to each other on the tree. For example, 'frog' might be in the same branch as 'toad'. The branch containing 'frog' and 'toad' would be next to the branch containing 'lizard', but far from the branch containing 'table', and even farther from the branch containing 'dream'. A least common subsumer is the closest word that is a parent of both synsets.

The similarity metrics used include:

• Path Similarity: the shortest path between two given meanings (synsets) of a word in the word tree

• Leacock-Chordorow [12]:

$$-\log\left(\frac{length}{2*D}\right)$$

where length is the length of the path similarity and D is the maximum depth of the taxonomy

• Wu-Palmer [13]:

$$2*\frac{d(LCS)}{d(S_1)+d(S_2)}$$

where d(s) is a function giving the depth of a subsumer, LCS is the least common subsumer, and  $S_1$  &  $S_2$  are the two subsumers being compared.

## IV. RESULTS

## A. Novel Classifier Results

We chose two datasets: Puns [14] and ShortJokes [15]. We used the same negative dataset for both datasets [14]. The positive datasets were first truncated to consist of 4326 jokes each, the length of the negative dataset.

The positive and negative datasets were randomly mixed, and separated into training and testing sets, numbering 4326 and 480 potential jokes respectively.

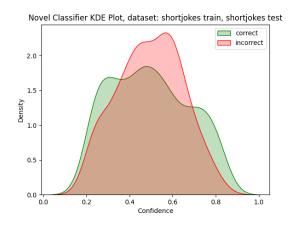

Fig. 1. Kernel Density Estimate Plot, 4 bins. The incorrect results were concentrated around predictions with low certainty, while the correct results show peaks at high certainty predictions.

We ran four experiments each for the novel classifier using bin numbers 2, 3, 4, 5, 6, and 7 – two using models tested on the same (Puns and ShortJokes) data set as the models were trained on, and two experiments using models tested on the other dataset.

As expected, the accuracy of the model's predictions were directly correlated to the confidence of the predictions. This held true for all choices of bin counts, and for models trained on both data sets - including models tested on the data set they were not trained on.

The ShortJokes trained models' predictions were less accurate than the Puns data set trained models' predictions for the lowest bin count (2 bins), for both test data sets. Conversely, the Puns data set trained models performed

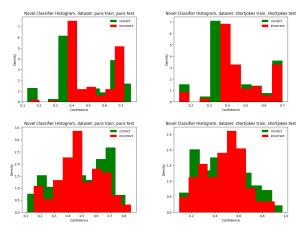

Fig. 2. Normalized Histograms of different Data Sets vs. 2 Bin models (top), and 7 bin models (bottom). The Puns trained model performed better using 2 Bins, the ShortJokes trained model performed better using 7 bins.

worse for the 7 bin model than the ShortJokes data set trained model.

We speculate that the larger count of similarity statistics resulting from the generally longer phrases the ShortJokes data set is composed of were not well distributed over a small bin count, and the opposite for the shorter-phrased Puns data set's statistics. A possible topic for future research would be setting the bin count based on the length of the input.

Drawing the training and test sets from different data sets did not affect the accuracy of the predictions. This indicates that this technique may be applicable to a wide variety of joke sets.

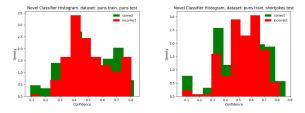

Fig. 3. 4 bin models drawn from the same vs. different datasets. Both models show only correct (green) predictions at the extreme right, allowing joke selection.

As noted above, the novel classifier generates a number between 0-1 indicating how confident the neural network is that the input is a joke. If almost all higher confidence predictions are correctly classified as jokes, correct predictions can be obtained by limiting the results to those extremes.

For example, if the amount of incorrect predictions with a confidence above a threshold of 0.8 is 0, and the amount of correct predictions above that confidence is positive, limiting our selection to those results with a confidence above that threshold will have a high probability of resulting in predictions that are all jokes.

Therefore, in addition to analyzing the accuracy of the entire prediction set, we experimented with different methods

of selecting the highest confidence predictions:

- 1) **Count**: Selecting the 5, 10 and 20 predictions with the highest levels of confidence.
- 2) **Percentage**: Selecting the top 1%, 5%, and 10% of predictions with the highest confidence.
- 3) **Standard Deviation**: Selecting the predictions within the top 1 standard deviation, the top  $\frac{1}{2}$  of a standard deviation, and the top  $\frac{1}{5}$  of a standard deviation of the predictions.

The most consistently accurate method of selecting the highest confidence predictions was selecting the 20 predictions with the highest confidence, using a bin count of 3. For both data sets, this resulted in 80% or higher accuracy among the selected predictions.

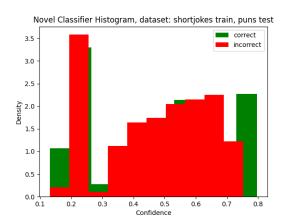

Fig. 4. 3 bins provide optimal performance.

# B. Control Classifier Results

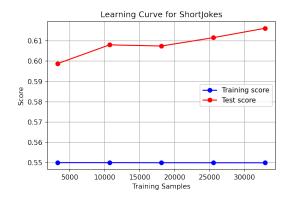

Fig. 5. Learning Curve - ShortJokes

The learning curve for the control classifier shows a textbook case of over-fitting. Given the current architecture, it tends to over-fit for certain use cases. Adding additional layers does not seem improve the model. The number of layers were limited to 100 to keep the training time at a minimum whilst still maintaining an optimal level of accuracy given the nature of the problem.

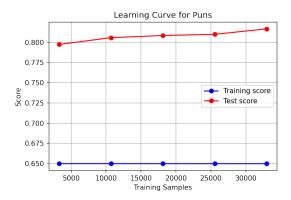

Fig. 6. Learning Curve - Puns

## C. Generated Joke Results

The model trained on the 'Puns' data set generated a large portion of output which exhibited offensive themes. This often involved profane language, sexism, or racism. The short jokes data set was relatively free of such content, and so were the results.

After generation of a large corpus of phrases, the transformer model did not generate many jokes which were notably funny. This was true for both the model trained on the 'Puns' data set and the model trained on the 'Short Jokes' data set. An example:

One day a man stabbed a policeman with his gardening knife and killed his wife, but it didn't really cut it for him.

Most results were not coherent:

- It is usually the bottom income plan at Vulture Ranch that helps with charge get weaned. These shows from flying dogs are usually fairly demanding and especially expensive today since they let you.
- Losing you to these celebrity chefs is probably the best job you've ever had.
- When you find out I was a Southerner who lived in a volcano, I could smell it on my jacket.

## V. CONCLUSION

The novel classifier successfully identified a subset of consistently humorous content over 20% more accurately than the control classifier, for both data sets. This indicates a fundamental correspondence between the nature of humor and the similarity between words. While not attempted in our work, adding the results of the control classifier as a further input into the novel classifier may further improve the results.

However, we were unsuccessful in generating consistent humorous content using the transformer, and much of the results were incoherent. This may be a result of our use of GPT-2. Use of GPT-3 and the soon to be released GPT-4 transformer based neural networks may garner better results.

Additionally, our method has demonstrated the following areas for improvement:

- Converting the candidate sentences into statistics was time consuming. This could be ameliorated by a faster computer.
- The transformer sentence generation was limited by the memory constraints imposed by the computing environment. This necessitated multiple calls to the transformer.
- 3) The novel humor classifier is constrained to comparing words with the same part of speech (nouns to nouns).

We hope that this work will serve as a basis for future developments in computer based humor generation.

#### ACKNOWLEDGMENT

This research is the result of work done as part of the Georgia Institute of Technology's Humor Genome Vertically Integrated Project (VIP), instructed by Professors Lew Lefton and Peter Ludovice. We would like to thank Professors Lefton and Ludovice for their time, support and advice - both within and outside of the framework of the Humor Genome Project. We would especially like to thank Professor Lefton for meeting with and guiding our team in writing this paper.

We would like to thank the 2019 Humor Genome VIP ML team for use of their data sets, and to Hazel Jiang for providing us with the original sources of those data sets.

We would like to give special thanks to Mrs. Raquel Dalin, whose supervision of the Dalin family children and household enabled her husband to participate in this research.

Finally, Mr. Dalin would like to give thanks to G-d, who gave us life, and sustained us, and brought us to this day.
